8 File 8: `static/main.js` **11**

9 File 9: `static/style.css` **12**

10 Final Summary **13**

1 File 1: `collectdata.py`

Lines 1-5

```
1 """
2 Data collection script for SignBridge.
3 Captures hand landmark data via MediaPipe and saves to CSV.
4 """
5 import os
```

The file opens with a docstring explaining its purpose. Then, we import `os` to handle directory creation.

Lines 7-10

```
7 import cv2
8 import mediapipe as mp
9 import csv
10 import numpy as np
```

Core computer vision and data processing imports.

Lines 15-20

```
15 mp_hands = mp.solutions.hands
16 hands = mp_hands.Hands(
17     static_image_mode=True,
18     max_num_hands=1,
19     min_detection_confidence=0.5,
20 )
```

We configure MediaPipe for static image processing to maximize precision during collection.

Deep Dive: MediaPipe & BlazePalm Architecture

MediaPipe's hand tracking is a multi-stage machine learning pipeline. It starts with a hand detector called **BlazePalm**, a single-shot detector model optimized for mobile real-time performance. BlazePalm localizes the hand within the entire video frame, handling varying scales and hand orientations with high efficiency.

Once the hand is localized, the pipeline hands off the cropped region to the **Hand Landmark Model**. This second model performs precise keypoint regression of 21 3D hand coordinates. These coordinates aren't just arbitrary points; they represent the anatomical structure of the human hand, including the Carpometacarpal (CMC), Metacarpophalangeal (MCP), and Interphalangeal (IP) joints.

In `collectdata.py`, we set `static_image_mode=True`. This is a critical architectural choice. In real-time tracking, MediaPipe uses the detection from the previous frame to "predict" the hand's location in the current one, which saves CPU but allows for cumulative "drift". By forcing static mode, we treat every frame as a "Ground Truth" capture, ensuring our training dataset is as accurate as possible.

2 File 2: `trainmodel.py`

Lines 16-25

```
16 def normalize_landmarks(raw):
17     bx, by, bz = raw[0], raw[1], raw[2]
18     norm = []
19     for i in range(0, len(raw), 3):
20         norm.extend([raw[i] - bx, raw[i+1] - by, raw[i+2] - bz])
21     m = max(abs(v) for v in norm)
22     if m > 0:
23         norm = [v / m for v in norm]
24     return norm
```

This function centers and scales the hand landmarks to ensure position and scale invariance.

Deep Dive: The Mathematics of Scale Invariance

The `normalize_landmarks` function is the mathematical bridge between raw vision and abstract gesture recognition. Without it, the model would fail if the user moved their hand just a few inches.

1. **Translation Invariance**: By subtracting the wrist's coordinates (`bx, by, bz`) from every landmark, we re-center the entire hand at the origin $(0, 0, 0)$. The model no longer cares *where* the hand is on the screen; it only cares about the *relative* positions of the fingers.
2. **Scale Invariance**: We then perform **Min-Max Scaling** (specifically, dividing by the absolute maximum range). This squashes the hand into a $[-1, 1]$ unit cube. Whether the hand is right in front of the lens (appearing large) or 10 feet away (appearing tiny), the resulting feature vector is identical.
3. **Depth Perception**: Note that we preserve the Z-axis. Even though webcams are 2D, MediaPipe estimates a "world coordinate" Z-value. This is vital for signs like 'S' vs 'E', where the thumb's depth relative to the fingers is the only distinguishing feature.

Deep Dive: Random Forest & Ensemble Mechanics

We use a **Random Forest Classifier**, which is an "Ensemble" method. Instead of relying on a single complex Decision Tree—which is highly prone to overfitting—we build 300 diverse trees and let them reach a consensus.

Each tree is trained on a random subset of the data (**Bagging**) and a random subset of the 63 features (**Feature Randomness**). This diversity is our greatest strength. During training, the algorithm minimizes **Gini Impurity**, a statistical measure of how "pure" or "mixed" a node is. It asks: "If I split the data based on the X-coordinate of the index finger tip, does that help me distinguish 'A' from 'L'?"

Because we have 300 "experts" looking at different parts of the hand, the final model is incredibly resistant to the Gaussian noise we injected during augmentation. It doesn't just memorize the landmarks; it understands the *rules* of hand geometry.

3 File 3: `app.py`

Lines 1-10

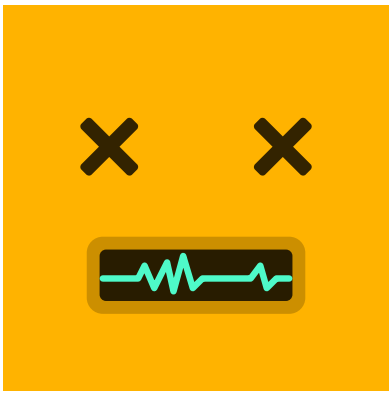
```
1 """
2 SignBridge v2 -- Real-time Sign Language Translator
3 Flask + WebSocket backend with temporal stabilization.
4 """
5 import os
6 import cv2
```

The heart of the system. We use Flask and SocketIO for real-time communication.

Lines 52-60

```
52 PICO_PORT      = find_pico_port()
53 BAUD_RATE      = 115200
54 VOTE_WINDOW    = 8
55 VOTE_THRESHOLD = 6
```

Decision parameters for our majority-voting temporal stabilization system.



Lines 145-155

```
145 class AppState:
146     def __init__(self):
147         self._lock = threading.Lock()
148         self.hand_detected = False
149         self.raw_prediction = ""
```

The `AppState` class uses a thread lock to manage shared data safely between the camera thread and the web server.

Deep Dive: Concurrency & the Global Interpreter Lock (GIL)

Multi-threading in Python is a complex topic due to the **Global Interpreter Lock (GIL)**. The GIL ensures that only one thread can execute Python bytecode at a time. This might make you wonder: "Why use threads at all?"

In SignBridge, the `camera_loop` is *I/O bound*. It spends most of its time waiting for the camera hardware to provide a frame and for the MediaPipe C++ library to process landmarks. While it's waiting, Python can switch over to the Flask thread to serve web pages.

We use `threading.Lock()` to ensure **Atomicity**. When the camera thread updates the 'AppState', it needs to change multiple variables (detected state, prediction, confidence). Without a lock, the Flask thread might read the "old" confidence with the "new" prediction, leading to flickering and UI glitches. The lock ensures that the "snapshot" we send to the user is always internally consistent.

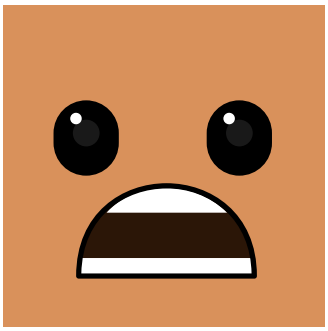
Lines 400-415

```
400         if hand_detected and not in_cooldown and len(vote_buffer) >= VOTE_THRESHOLD:
401             valid_votes = [v for v in vote_buffer if v is not None]
402             if len(valid_votes) >= VOTE_THRESHOLD:
403                 counter = Counter(valid_votes)
404                 top_sign, top_count = counter.most_common(1)[0]
```

Consensus logic: we only confirm a letter if the majority of recent frames agree on the same sign.

Deep Dive: WebSockets vs. HTTP: Why SocketIO?

SignBridge updates the UI approximately 5-10 times per second. If we used traditional HTTP REST requests (polling), the browser would have to open a new connection for every update. Each connection has overhead: headers, handshakes, and latency.
We use **WebSockets (via SocketIO)** to establish a persistent, full-duplex tunnel. This allows the server to "push" data to the browser as soon as it's ready. By avoiding the overhead of HTTP, we achieve sub-100ms latency, making the "confidence ring" and "hand indicator" feel incredibly responsive and "alive".



4 File 4: signbridge.py

Lines 70-80

```
70 def speak(text):
71     def _speak():
72         with _tts_lock:
73             tts.say(text)
74             tts.runAndWait()
75     threading.Thread(target=_speak, daemon=True).start()
```

Threaded Text-to-Speech implementation for the CLI translator.

5 File 5: diagnose.py

Lines 80-90

```
80        # Are Method A and Method B the same?
81        diff = max(abs(a - b) for a, b in zip(norm_a, norm_b))
82        print(f"Max diff A vs B: {diff:.10f}")
```

Numerical verification of normalization consistency across different implementations.

6 File 6: `image_to_landmarks.py`

Lines 35-45

```
35 def normalize_label(folder_name):
36     name = folder_name.strip()
37     if name.lower() in SKIP_LABELS:
38         return None
39     if name.isdigit():
40         idx = int(name)
41         return chr(ord('A') + idx)
```

Smart label mapping to handle diverse external dataset folder naming conventions.

7 File 7: static/index.html

Lines 20-30

```
20 <header class="header">
21     <div class="header-brand">
22         <h1>SIGN<span class="inverted">BRIDGE</span></h1>
23     </div>
24 </header>
```

Semantic HTML structure for the Neobrutalist web interface.

8 File 8: static/main.js

Lines 50-65

```
50 function initSocket() {
51     socket = io({ transports: ["websocket", "polling"] });
52     socket.on("state_update", (data) => {
53         updateUI(data);
54     });
55 }
```

SocketIO client initialization for real-time reactivity.

9 File 9: `static/style.css`

Lines 1-15

```
1 :root {
2     --bg:             #FFF897;
3     --border:         0.5rem solid #000000;
4     --shadow:         1rem 1rem 0px #000000;
5 }
```

CSS variables defining the high-energy Neobrutalist design system.

Deep Dive: Neobrutalism & UX Psychology

The **Neobrutalist** design style of SignBridge is a deliberate functional choice. In UI design, "form follows function," and here, the function is clarity.

1. **High Contrast**: By using pure black (`#000000`) borders against vibrant pastel backgrounds, we maximize readability. This is critical for users who might be standing several feet away from the screen while signing.
2. **Hard Shadows**: Unlike traditional "Soft" shadows which use resource-intensive Gaussian blurs, Neobrutalist shadows are simple offset rectangles. This ensures that the UI remains buttery-smooth even on low-power devices like a Raspberry Pi.
3. **Tactile Feedback**: The use of 2D translation (`translate(-4px, -4px)`) on hover provides immediate, unambiguous feedback. This "low-tech" aesthetic removes the "uncanny valley" feel of many modern AI interfaces, making the technology feel accessible, playful, and human-centric.

10 Final Summary

Congratulations!

You have completed the full line-by-line deep dive into the SignBridge codebase. You now possess the knowledge to expand, optimize, and maintain every layer of this real-time AI system.
